EXECUTIVE SUMMARY

Urban Indian Health Institute (UIHI) analyzes data from the American Community Survey and the National Vital Statistics System to estimate proportions for 33 health indicators. With this data, UIHI creates Community Health Profiles for service areas throughout the United States.

This Community Health Profile contains sociodemographic, mortality, and maternal and child health data on American Indians and Alaska Natives (AI/ANs) that has been aggregated over a five-year period from the Tulsa service area, which includes Tulsa county. The sociodemographic data as well as the mortality data are from 2010-2014, and the maternal and child health data are from 2008-2012.

The county data shows that urban Indians living in the Tulsa service area frequently experience higher proportions of poverty and disparities in employment, education, food security, mortality, and maternal and child health when compared to their Non-Hispanic White (NHW) counterparts. As this profile may show, there is still work to be done from local, state, and federal entities to collect quality, accurate data. Urban Indian Health Programs should work closely with their local and state health jurisdictions to access the most current data and, where possible, urge better tracking of demographics to inform care.

KEY FINDINGS:

Compared to NHW, urban AI/AN in these counties are:

- **More than one and a half times as likely to experience unemployment,**
- **More than one and half times as likely to have no high school diploma or equivalent degree,**
- **Twice as likely to participate in food assistance programs,**
- **More likely to die in infancy, at a rate nearly two and a half times higher, and**
- **Nearly one and a half times more likely to give birth prematurely**

TULSA SERVICE AREA

INTRODUCTION

The health needs of America's urban Indian population present unique challenges. Across the U.S., an examination of the health outcomes of urban Indians show disproportionately high incidence of disease, co-morbidity, and mortality, particularly for urban Indian mothers. This is significant because, of the 5.2 million Americans who identify as American Indian/Alaska Native (AI/AN), 71% live in urban areas. To meet their health needs, numerous health and social service programs are providing culturally appropriate and holistic care. Many offer services that are grounded in indigenous knowledge and bring Western and traditional medicine together.

As Urban Indian Health Programs and Native health organizations strive to provide the highest-quality care to urban Indians, relevant data are needed. Since 2000, UIHI has created Community Health Profiles for 35 cities where urban Indian people reside, and, in 2018, nine cities were added. This individual Community Health Profile details the data for the Tulsa service area, which includes Tulsa county.

What is an urban Indian?

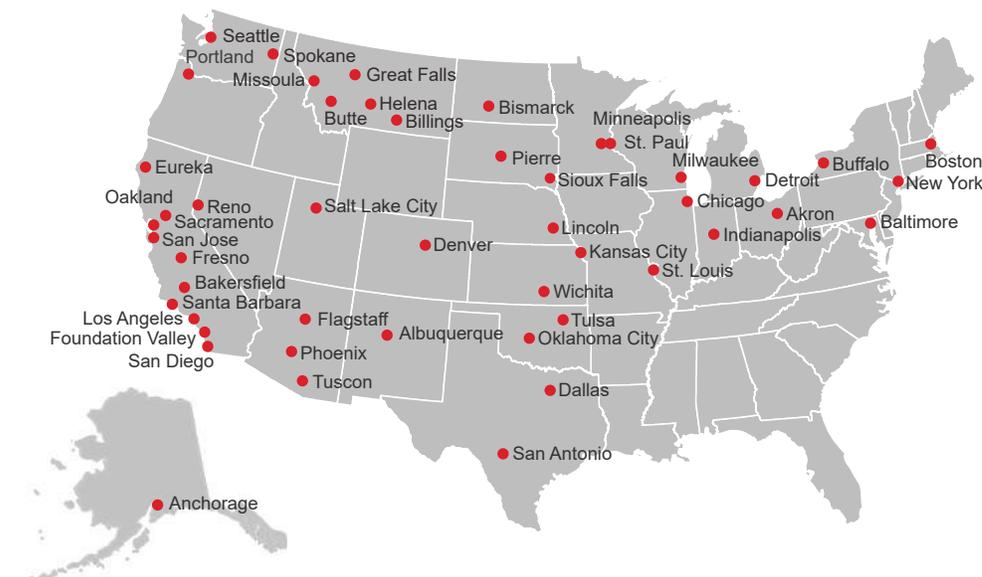

Urban Indians are tribal members who are currently living outside of federally-defined tribal lands in U.S. cities.¹ For many AI/AN communities, systemic issues such as racism, poverty, and poor education have given rise to health disparities.^{2, 3} For urban Indians in particular, government policies that forced relocation in the 1950s and termination policies that forced assimilation into non-Native culture, have had long-term health effects.² Today, AI/ANs come to the city for educational, employment or housing opportunities, and health-care needs, resulting in an indigenous urban population that is diverse and inter-tribal.

71% of American Indians and Alaska Natives live in urban areas

SERVING THE HEALTH NEEDS OF URBAN INDIANS

Programs across the United States are providing holistic health care to urban Indians, including private, non-profit corporations receiving partial funding from the Indian Health Service as well as social- and faith-based organizations. UIHI defines the service areas of these programs as Urban Indian Health service areas and are illustrated below in Map 1.

Map 1. Urban Indian Health Service Areas

HOW TO USE THIS REPORT

Improving community health through effective planning and decision making requires good information about the factors that influence the health status of community members.² While limited in scope and restricted to available and usable data, this report provides valuable information for service providers serving an urban Indian population with unique needs and greater risk factors. The information provided here is intended to supplement other local data available to your organization.

Program Planning

Data in this report can be used by urban Indian organizations to identify health priorities, allocate resources, and guide the development of innovative programs.

Funding

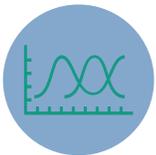

Data and figures help tell the story of existing health disparities in the AI/AN population compared to NHWs. This report may be useful to include as information for grant applications and other funding opportunities. It can also be cited as a reference.

Identifying Gaps in Data

This report may reveal the need to close current gaps in nationally-collected data. Providers may want to consider pushing their jurisdictions to link other relevant data to help correctly classify AI/ANs in state death records.^{4,5} Another way to improve data collection is by oversampling AI/ANs in national surveys, which provides sufficient statistical power to allow for more stable estimates.

Research

Data in this report can be used to generate additional hypotheses for future studies, evaluations, or assessments.

METHODS AND DATA

This report includes information from residents of Tulsa County as well as data from the 2010 U.S. Census, American Community Survey, and National Vital Statistics System. There are limitations to this data particularly due to variations in how race is defined and collected.

Analysis

A list of indicators for the community health profile was selected after an analysis of the available data sources. For each indicator, prevalence or incidence was calculated for the AI/AN population and compared with the NHW population. Since NHWs are the racial/ethnic majority, this population was chosen as the comparison group. The AI/AN population was defined as AI/AN only, and in combination with other races, unless otherwise indicated. The NHW population was defined as White only and excluded the Hispanic population unless otherwise indicated. Results were calculated using aggregated data over a five-year period. Which added stability to estimates and protected individual privacy.

In some instances, confidence intervals—ranges of numbers used to assess the accuracy of a point estimate and measure the variability in data—were calculated and used to show differences in outcomes for specific indicators. The point estimate may be a rate, such as a death rate, or a frequency, such as a percent of individuals living in poverty. Confidence intervals account for the uncertainty that arises from the natural variation inherent in the world around us.

Confidence intervals also account for the difference between a sample from a population and the population itself. For analyses included in this report, confidence intervals were calculated at a p-value of <0.05 , which is a 95 percent confidence level. This means that 95 times out of 100 the confidence interval captures the true value for the population. Differences in outcomes were called significant if confidence intervals of the study group (AI/AN) did not overlap with the comparison group (NHW). Data analysis for indicators were analyzed using the statistical software SAS version 9.4.

Data Limitations

Although data analysis and assessment of results were conducted for 33 indicators, data limitations were found. In some instances, the number of cases or sample size was limited, data collection excluded AI/AN in combination, or there was possible racial misclassification of AI/AN. These limitations impact the analysis and prevent or limit the reporting of results.

Frequently, data were only available for AI/ANs alone and not inclusive of AI/ANs who also identify with another race or ethnicity. Therefore, the estimates provided in this report may be an underestimation of the true value of the outcome or risk factor for any indicator analyzed.

Racial misclassification, particularly for demographic and mortality data, can greatly underestimate the true rate of disease, risk factor, or outcome. AI/ANs are especially likely to experience problems of incorrect classification on death certificates. Therefore, true mortality rates among AI/ANs are assumed to be higher than reported.^{5,6}

DATA SOURCES

2010 U.S. Census

The U.S. Census takes place every 10 years and provides official population counts for individuals living in the United States. It also presents information on age, race, Hispanic origin, and sex. In 2010, the U.S. Census allowed individuals to self-report belonging to more than one racial group.

When determining a population count, this report considers people to be AI/AN if they report AI/AN as their only race or if they report being AI/AN in combination with other races. Some Census statistics are not easily accessible when including individuals who report multiple races, so, for these indicators, only individuals who report AI/AN alone are included.

For more information about the U.S. Census, visit: www.census.gov.

American Community Survey

The American Community Survey (ACS) is a nationwide, continuous survey that collects demographic, housing, social, and economic data every year. To provide reliable estimates for small counties, neighborhoods, and population groups, the ACS provides 1-, 3-, and 5-year aggregate estimates. Estimates for this report are from aggregated data from 2010-2014.

Race is self-reported in ACS, with similar race categories as the U.S. Census. However, some ACS data are not easily accessible for multiple racial groups. Therefore, ACS data are reported for AI/AN alone in this report. ACS estimates in this profile are not adjusted for age. Observed differences in estimates may be due to a true difference in rates or due to differences in age distribution in the population.

For more information about the ACS, visit: www.census.gov/acs.

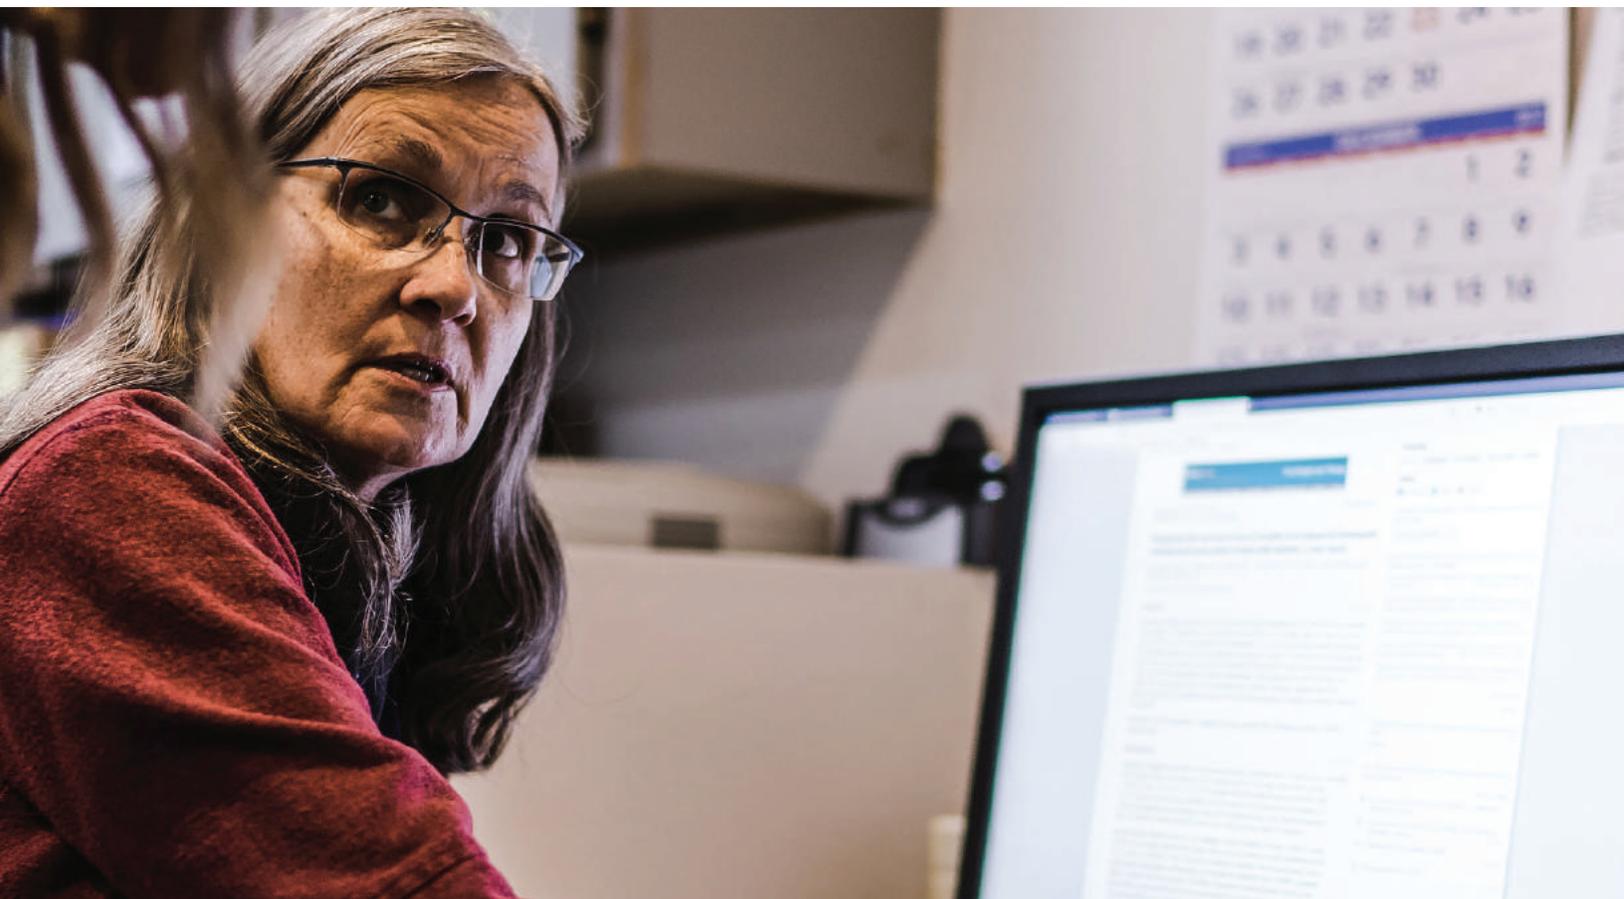

National Vital Statistics System

Mortality data from the National Vital Statistics System (NVSS) are generated from death certificates. The five most recent years for which complete mortality data were available was from 2010-2014. The five most recent years for which complete infant mortality data were available was from 2008-2012. All mortality data are age-adjusted to the U.S. population for the year 2000. Age-adjusted death rates are useful when comparing different populations because they remove the potential bias that can occur when comparing populations with different age distributions. For example, AI/ANs historically are a younger population than other race groups.

Birth certificate data from NVSS data files include all documented births occurring within the United States as filed in each state. These data include demographic information about parents, information on the infant, the mother's risk factors, and information on the birth. The five most recent years for which complete natality data was available was from 2008-2012.

Since not all states allow individuals to identify as more than one race, National Center for Health Statistics (NCHS) releases bridged-race population estimates for calculation of rates. As a result, estimates in this report may not match local and county estimates because of differing projection methods.

For more information about NVSS, visit: <http://www.cdc.gov/nchs/nvss.htm>

SOCIODEMOGRAPHICS

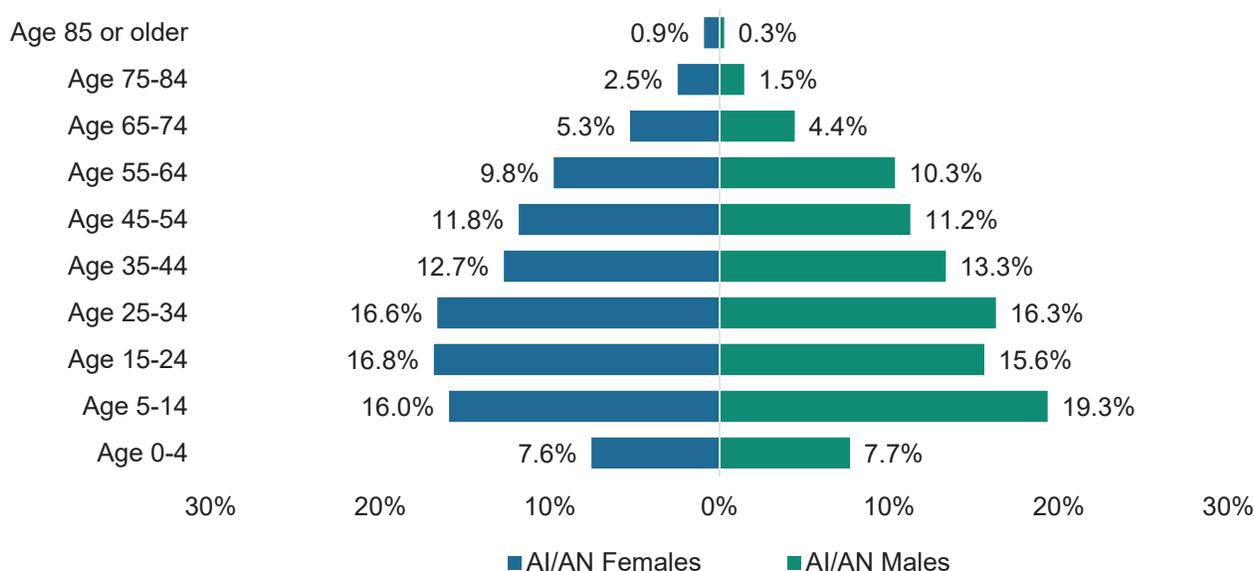

Introduction

The health of an individual or a population is largely determined by where they live, work, play, and learn. Race and economic status also play key roles.^{7,8} Decades of research show a relationship between greater social disadvantage and poorer health. Race, lack of access to education, unemployment, poverty, and housing all create inequities between urban Indian and Non-Hispanic White populations.⁷ This section presents data on measures of demographics and social determinants of health to illustrate the disparities between AI/ANs and NHWs.

Age and Gender

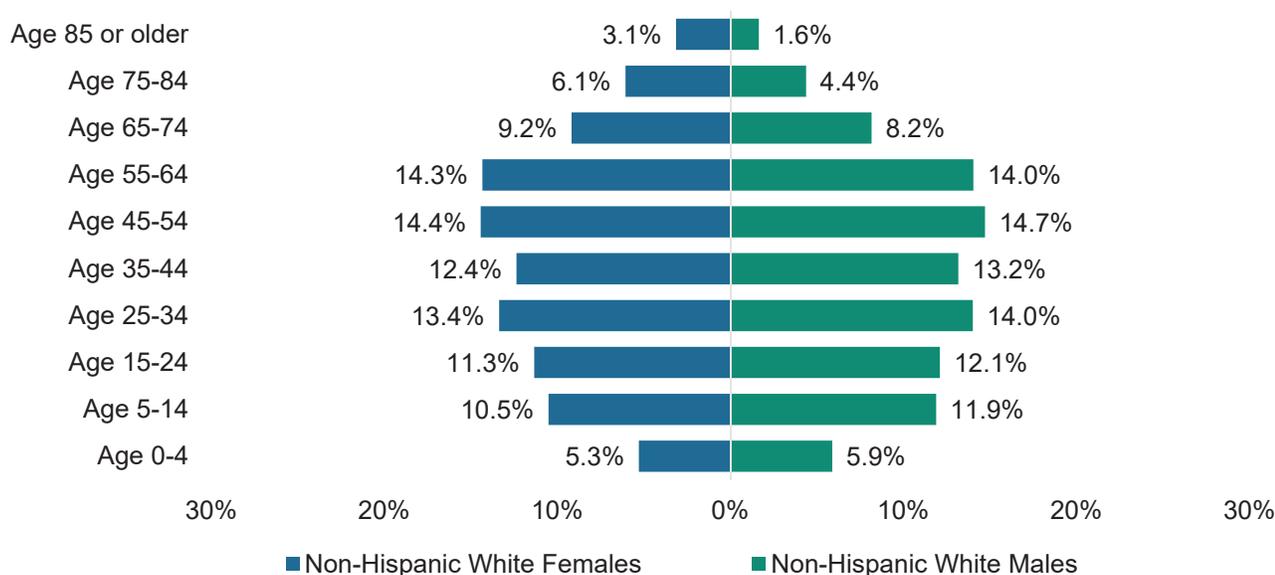

Relative to the NHW population, the AI/AN population in the Tulsa service area was younger (Figure 1; Figure 2). Forty one and a half percent of AI/ANs were under the age of 25 years, compared with 28.5% of NHWs. In contrast, 7.5% of AI/ANs were over the age of 65 years, compared with 16.3% of NHWs.

Source: American Community Survey, 2010-2014

TULSA SERVICE AREA

Race

As shown in Figure 3, an estimated 28,938 (4.7%) individuals identified as AI/AN alone in the Tulsa service area, and an estimated 64,236 (10.4%) individuals identified as AI/AN alone or in combination with one or more races (data not shown). Those who identified as White alone comprised the largest proportion (71.6%) of the total population (616,128) in the Tulsa service area. In addition, Black or African American was the second largest population identified, making up 10.2% of the total population.

Figure 3. Population by Race, Tulsa Service Area, 2010-2014

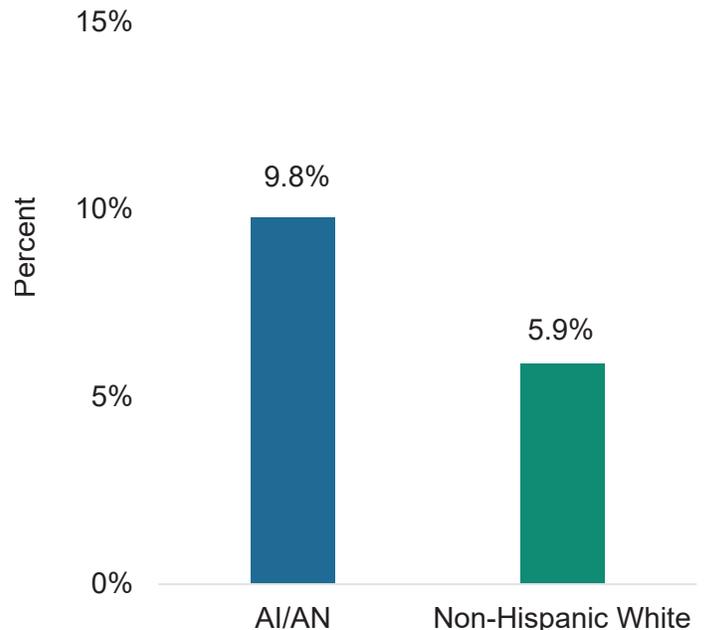

Source: American Community Survey, 2010-2014

Unemployment

Extensive evidence has shown that unemployment has a negative effect on health.⁹ Unemployed individuals may experience financial insecurity and are more likely to lack health insurance coverage.¹⁰ The percent of unemployed AI/ANs over 16 years of age was 1.7 times higher than NHWs (9.8% vs 5.9%; Figure 4).

Figure 4. Civilian Labor Force, Tulsa Service Area, 2010-2014

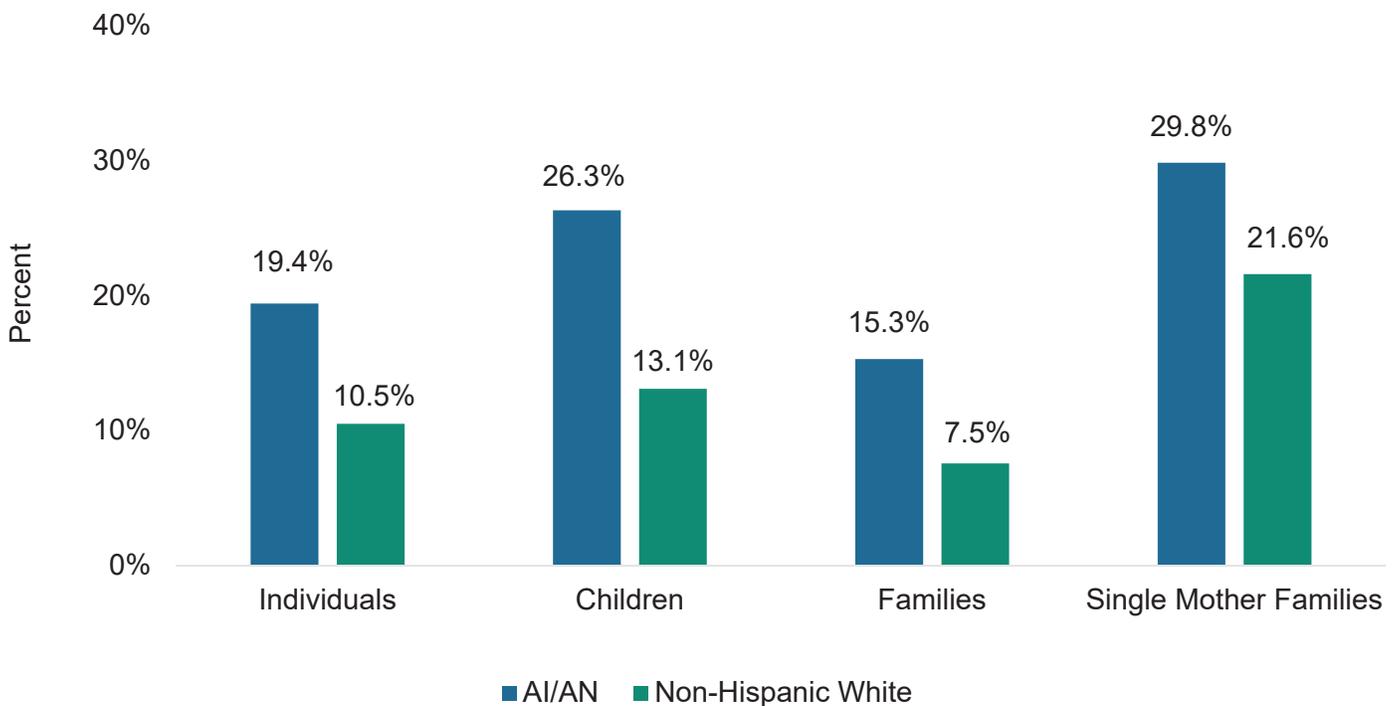

Source: American Community Survey, 2010-2014

Poverty

Poverty limits access to healthy foods, quality housing, economic opportunities, and adequate health care.^{11, 12} These foundational social and economic factors are inextricably connected to health outcomes. The impacts of poverty on a child’s health and well-being can be detrimental, including negative effects on early childhood and secondary academic achievement.^{13, 14} In this report, poverty is defined as an annual income less than 100% of the federal poverty level. For example, in 2017, 100% of the federal poverty level for a family of four was no more than \$24,600.¹⁵

In the Tulsa Service Area, nearly one in five AI/AN individuals lived in poverty (19.4%), compared to just 10.5% of NHWs (Figure 5). The percentage of AI/AN children experiencing poverty was higher than NHW children. Approximately one in four AI/AN children aged 17 and under (26.3%) with an income below the federal poverty level. This proportion is two times that of the NHW population (13.1%). In addition, 15.3% of AI/AN families lived in households with an income below the federal poverty level. This is two times higher than the proportion of NHWs (7.5%). Finally, among those AI/AN families in households headed by single mothers, nearly one-third lived in poverty (29.8%), which is 1.4 times higher than the proportion of NHW families headed by single mothers (21.6%).

Figure 5. Income Below the Federal Poverty Level in Past Year, Tulsa Service Area, 2010-2014

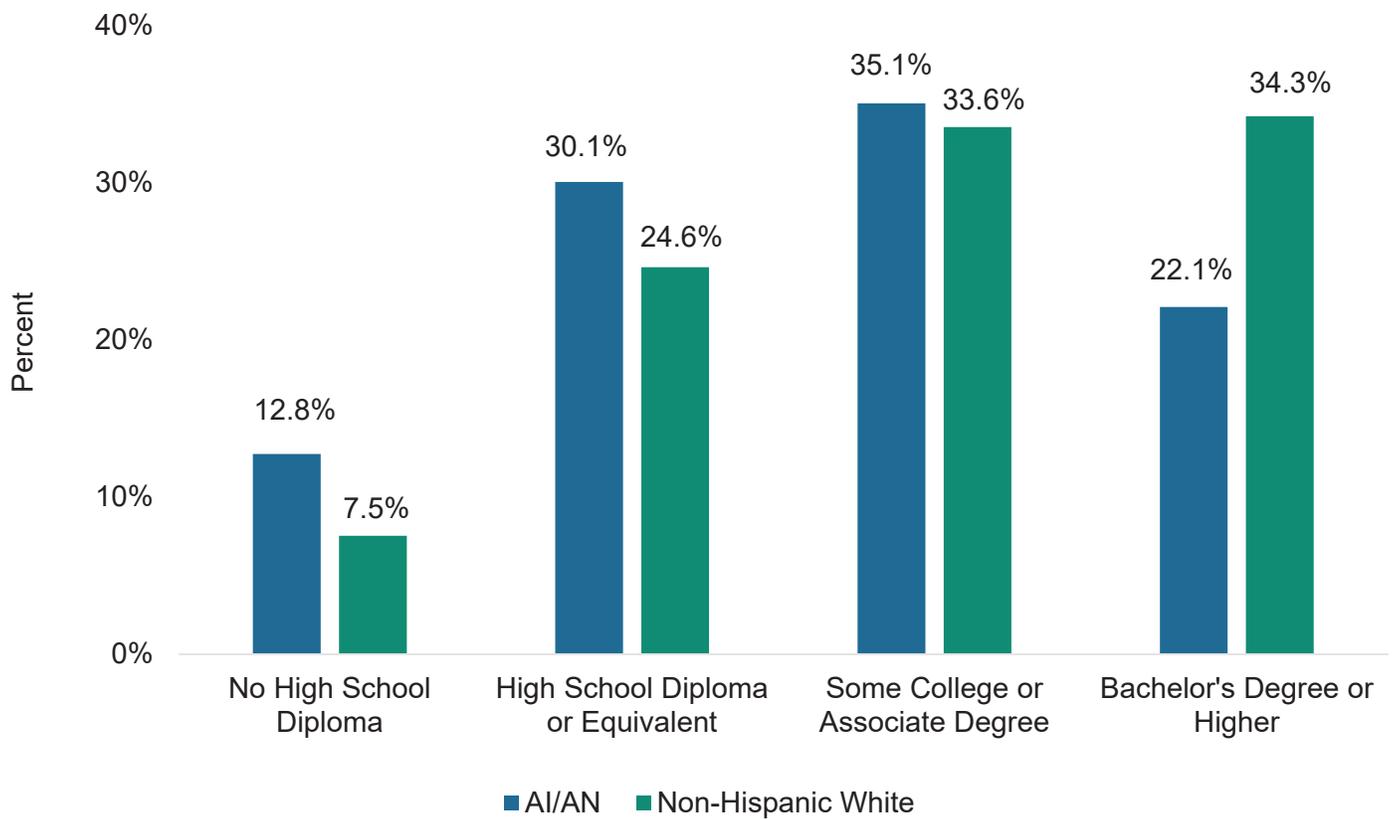

Source: American Community Survey, 2010-2014

TULSA SERVICE AREA

Educational Attainment

The relationship between education and health is well documented.^{16, 17} Disparities in life expectancy by level of education are found among all demographic groups and are arguably increasing over time.¹⁷ A higher proportion of AI/ANs aged 25 and older had not completed high school or passed the General Educational Development (GED) exam (12.8%) compared with the NHW population (7.5%; Figure 6). A lower proportion of AI/ANs (22.1%) reported a Bachelor's degree or higher as their highest level of education compared with the NHW population (34.3%). The proportion of AI/ANs that reported a Bachelor's degree or higher was 35.6% lower than NHWs.

Figure 6. Educational Attainment for the Population 25 and Older, Tulsa Service Area, 2010-2014

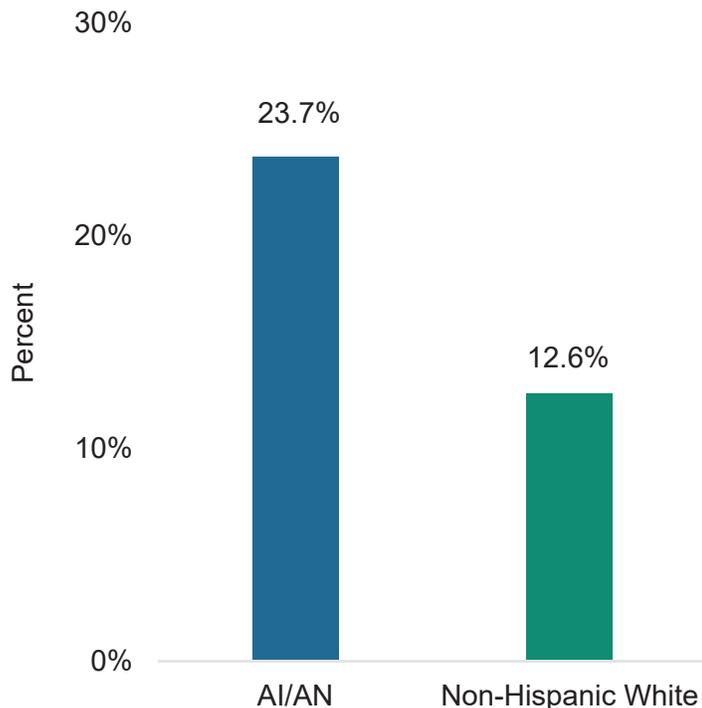

Source: American Community Survey, 2010-2014

Health Insurance Coverage

Those without health insurance coverage have higher mortality rates than those with coverage.¹⁸ Individuals without health insurance are also less likely to receive care and take longer to return to health after an unintentional injury or the onset of a chronic disease than those with health insurance.¹⁹

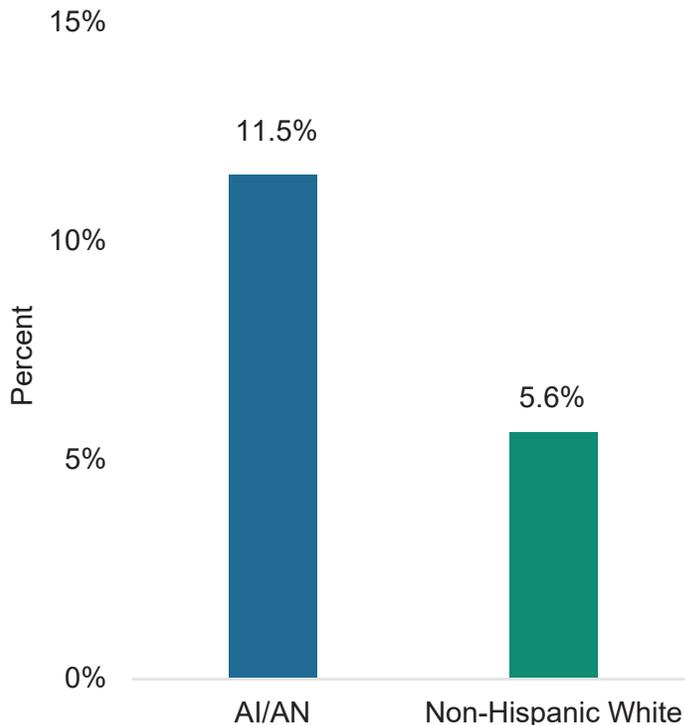

Nearly one in four AI/ANs under age 65 (23.7%) reported having no health insurance, a proportion 1.9 times higher than that of NHWs (12.6%; Figure 7). The proportion of uninsured AI/AN children under the age of 18 (11.5%) was 2.1 times higher than their NHW counterparts (5.6%; Figure 8).

TULSA SERVICE AREA

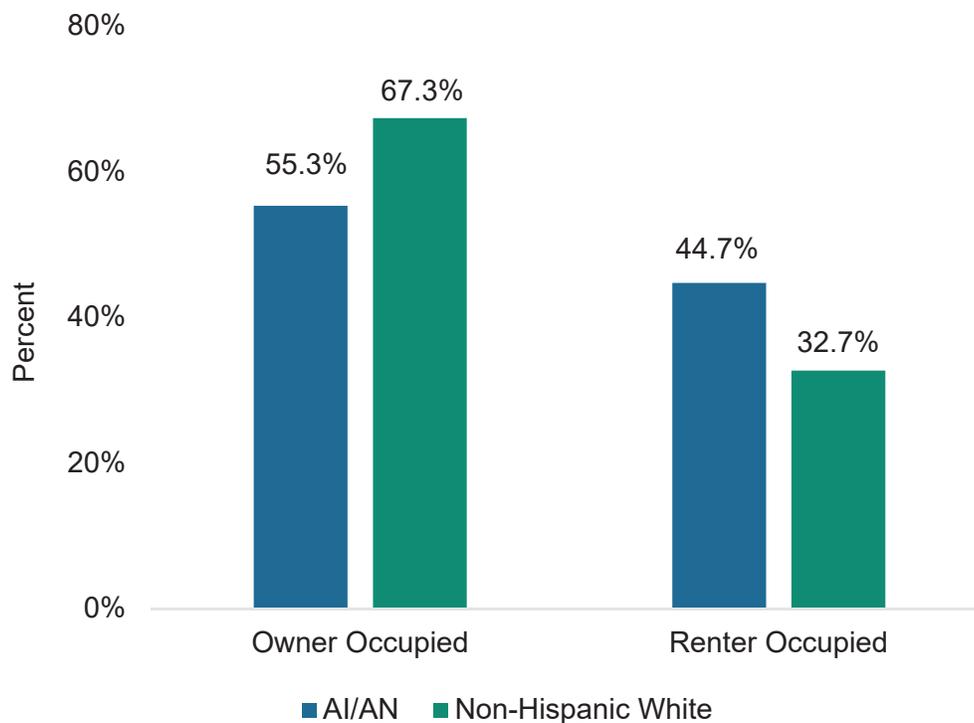

Housing

Several studies have found that home ownership is associated with many health benefits.²⁰

²¹ These benefits may be explained by the fact that homeowners likely experience higher socioeconomic status, fewer problems of overcrowding, and lower exposure to neighborhood violence. In contrast, renters are more likely to experience poorer self-reported health, higher proportions of coronary heart disease, and more risk factors, such as smoking.²²

Of all AI/AN households, 55.3% were owner occupied compared with 67.3% of NHW households (Figure 9). The proportion of home ownership among AI/ANs was 17.8% lower than NHWs. In contrast, 44.7% of all AI/AN households were renter occupied compared to approximately one-third of NHW households (32.7%). The proportion of renter occupation among AI/ANs was 1.4 times higher than NHWs.

Figure 9. Housing Tenure, Tulsa Service Area, 2010-2014

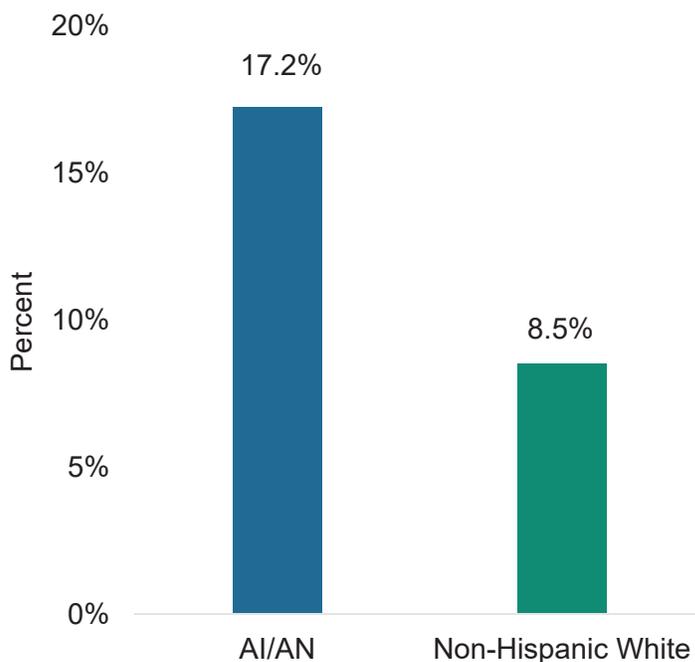

Source: American Community Survey, 2010-2014

Food Stamps

Households experiencing poverty are more likely to be food insecure.²³ As the largest food assistance program in the United States, the Supplemental Nutrition Assistance Program (SNAP), formerly known as the federal Food Stamp program, is a crucial part of the social safety net.²⁴ In most states, many households with an income below 130% of the federal poverty level are eligible to receive SNAP benefits.

In the Tulsa Service Area, 17.2% of AI/AN households received SNAP benefits in the past year (Figure 10). The proportion of SNAP participation among AI/ANs in this area was two times higher than NHWs (8.5%).

Figure 10. SNAP Use, Tulsa Service Area, 2010-2014

Source: American Community Survey, 2010-2014

MORTALITY

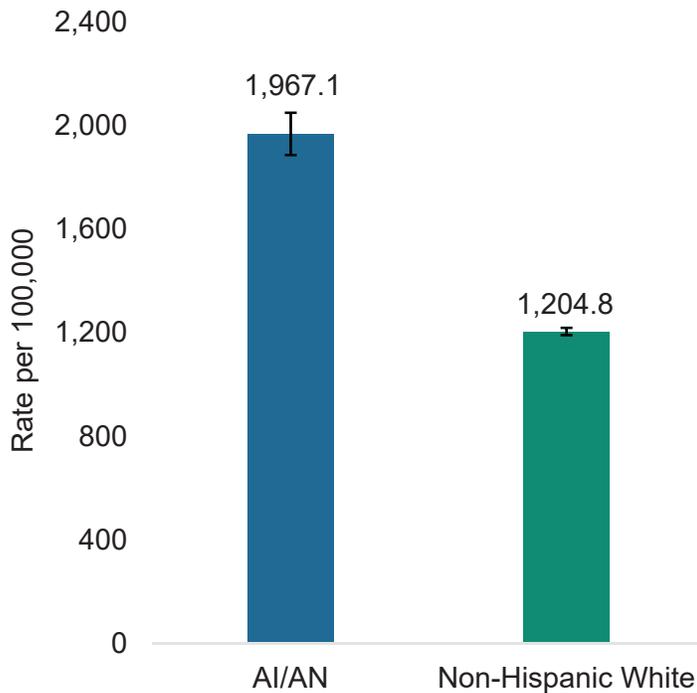

Introduction

Mortality data provide an indication of a community's or population's health and socioeconomic development status. Mortality data are also a key component to understanding population size, future growth, and change. Examining mortality data is one way to measure the burden of disease in a community or population. Tracking death rates may identify groups that are at an increased risk of premature death and may identify specific underlying causes of death that are more prevalent in certain populations. In addition, high mortality rates may indicate an issue with environmental, risk, and/or socioeconomic factors as well as communicable diseases. Relevant and accurate data are needed on the health of urban Indians. UIHI recommends local, state, and national organizations work to improve the quality and availability of data to serve this diverse and unique population.

All-Cause Mortality Rate

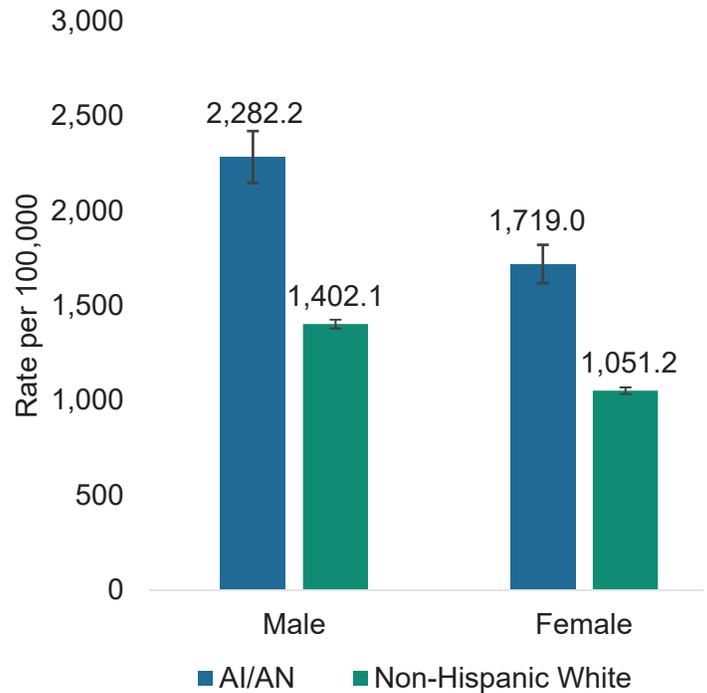

The all-cause mortality rate was 1.6 times higher for the AI/AN population than for the NHW population, a significant difference (Figure 11). The mortality rates for both males and females were 1.6 times higher among AI/ANs compared to their NHW counterparts (Figure 12). Additionally, the mortality rate for AI/AN men was 1.3 times higher than AI/AN women.

TULSA SERVICE AREA

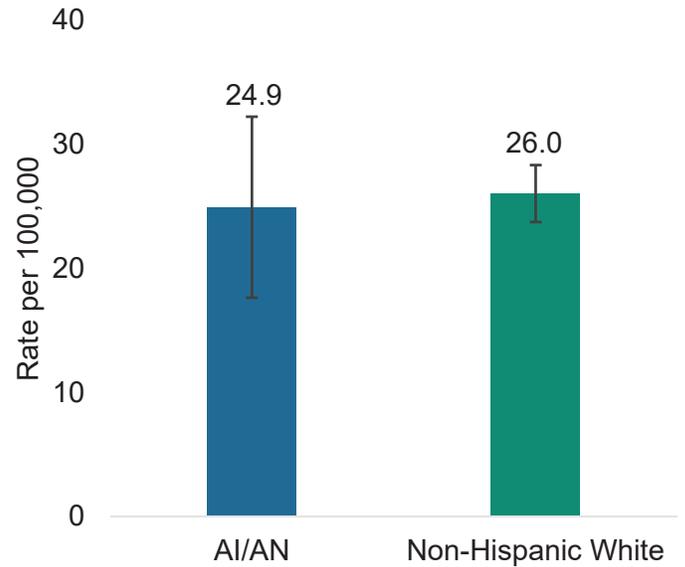

Suicide

In the Tulsa service area, the suicide rate for AI/ANs and NHWs were not statistically different (24.9 and 26.0 per 100,000; Figure 13). The suicide rates for males and females were not statistically different among AI/ANs and NHWs (Figure 14). The suicide rates were 3.0 times higher for AI/AN males compared to AI/AN females.

Homicide

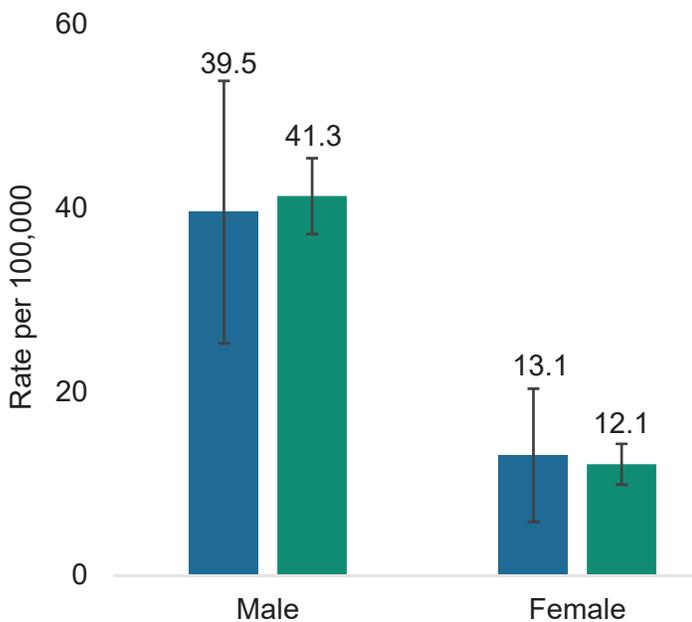

In the Tulsa service area, the homicide rate was not significantly different for AI/AN (6.4 per 100,000) compared to NHW (9.7 per 100,000; Figure 15).

Figure 13. Suicide Mortality Rate, Tulsa Service Area, 2010-2014

Unintentional Mortality

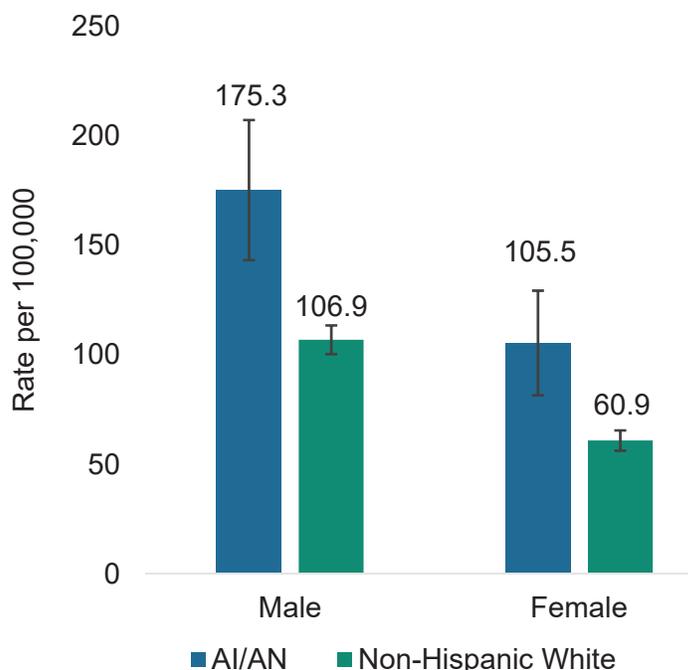

Unintentional mortality refers to deaths that can be attributed to an accident, such as a fall, or motor vehicle accident. In the Tulsa service area, the unintentional mortality rate was higher for AI/AN (139.3 per 100,000) compared to NHW (81.9 per 100,000; Figure 16). The proportion of unintentional mortality rates among AI/ANs was 1.7 times higher than NHWs. The unintentional mortality rates for males were 1.6 times higher for AI/ANs compared to their NHW counterparts and 1.7 times higher for AI/AN females when compared to NHW females (Figure 17). In addition, the unintentional mortality rate for AI/AN men was 1.7 times higher compared to AI/AN women.

MATERNAL AND CHILD HEALTH

Introduction

Understanding the state of maternal and child health (MCH) for urban Indians is key to creating the foundation for healthy children, mothers, and future generations. Tracking maternal smoking, gestational diabetes, prenatal care, and premature births can help urban Indian health organizations make the best decisions regarding programs for pregnant mothers and infants. As UIHI found in the Tulsa service area, disparities exist in most key indicators for MCH. The data in this section can be used to further examine why these health disparities exist and to consider programs to eliminate them.

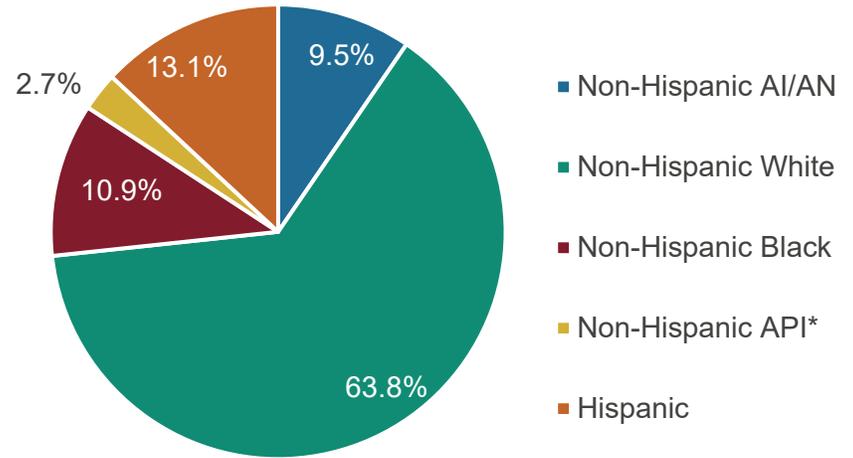

TULSA SERVICE AREA

Total Birth

From 2008 to 2012, there were a total of 65,909 births in the Tulsa service area. Among those births, 9.5% were identified as Non-Hispanic AI/AN alone (Figure 18). The largest proportions of births among the racial/ethnic groups were from NHW women (63.8%) and Hispanic women (13.1%). Non-Hispanic Blacks were approximately 10.9% and Non-Hispanic Asians and Pacific Islanders were 2.7% of all births.

Figure 18. Births by Race/Ethnicity, Tulsa Service Area, 2008-2012

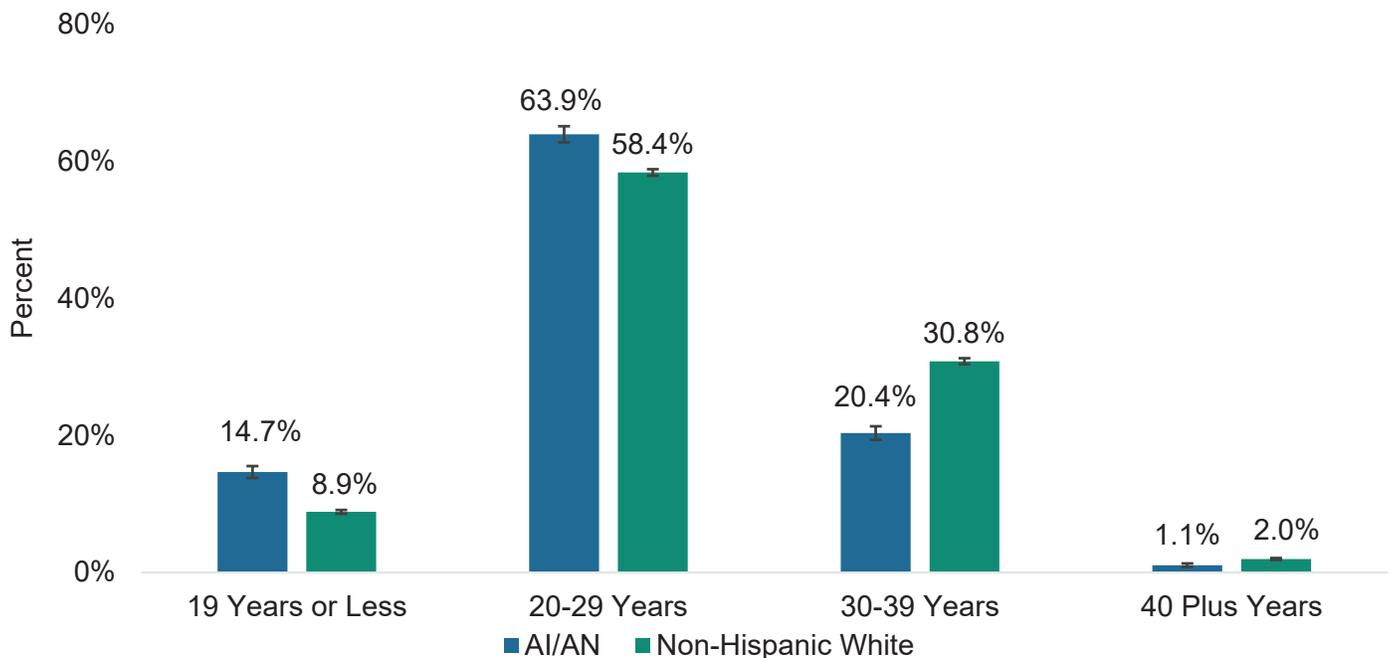

*API: Asian-Pacific Islander

Source: National Vital Statistics, Birth Certificates, 2008-2012

Age

In general, AI/AN women tend to give birth at younger ages than their NHW counterparts (Figure 19). In the Tulsa service area, 14.7% of all births among AI/AN women were to teenage women (less than 19 years of age) compared to 8.9% of NHW births. The proportion of births to teenage women was 1.7 times higher in AI/ANs compared to NHWs. In addition, 63.9% of all births among AI/AN women were to women in their 20s, compared to 58.4% among NHWs. Conversely, NHW women had more children in their 30s compared to AI/AN women (30.8% vs. 20.4%).

Figure 19. Births by Maternal Age Group, Tulsa Service Area, 2008-2012

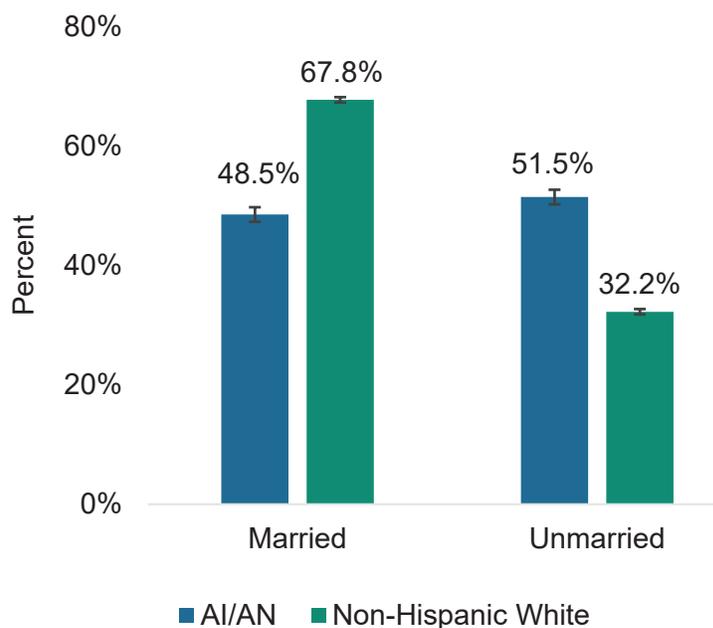

Source: National Vital Statistics, Birth Certificates, 2008-2012

Marital Status

In the Tulsa service area, 48.5% of all births to AI/ANs were to women who were married and 51.5% were to women who were not married (Figure 20). This was significantly different compared to NHWs in which 67.8% of births were to married mothers and 32.2% of births were to unmarried mothers. The proportion of births to unmarried women was 1.6 times higher in AI/ANs compared to their NHW counterparts.

Figure 20. Births by Marital Status, Tulsa Service Area, 2008-2012

Source: National Vital Statistics, Birth Certificates, 2008-2012

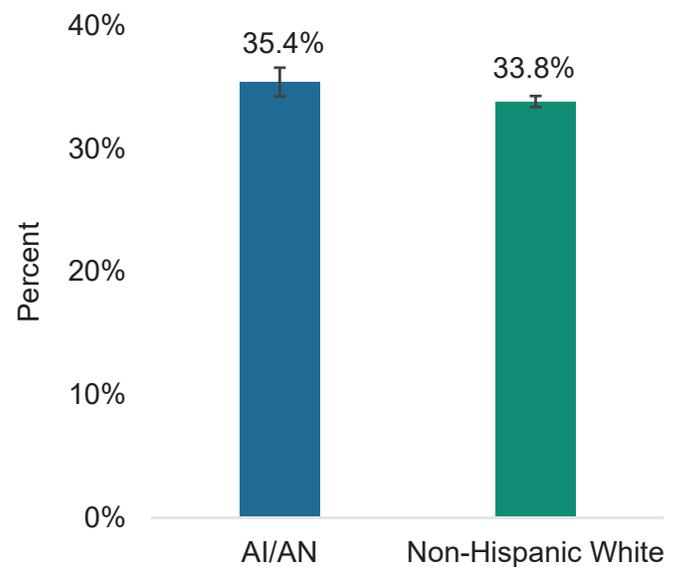

Cesarean Section

While cesarean sections can prevent maternal and infant mortality and morbidity, there is no advantage for women who have the procedure electively.^{25, 26} Possible complications of cesarean sections include infection, hemorrhage or increased blood loss, injury to organs, and extended hospital stay.^{27, 28} In a study exploring the effect of maternal age on cesarean section rates, rates of cesarean section were shown to increase with maternal age.²⁹ Pre-existing conditions that are more prevalent in older women, such as high blood pressure and diabetes, are risk factors for cesarean delivery.³⁰

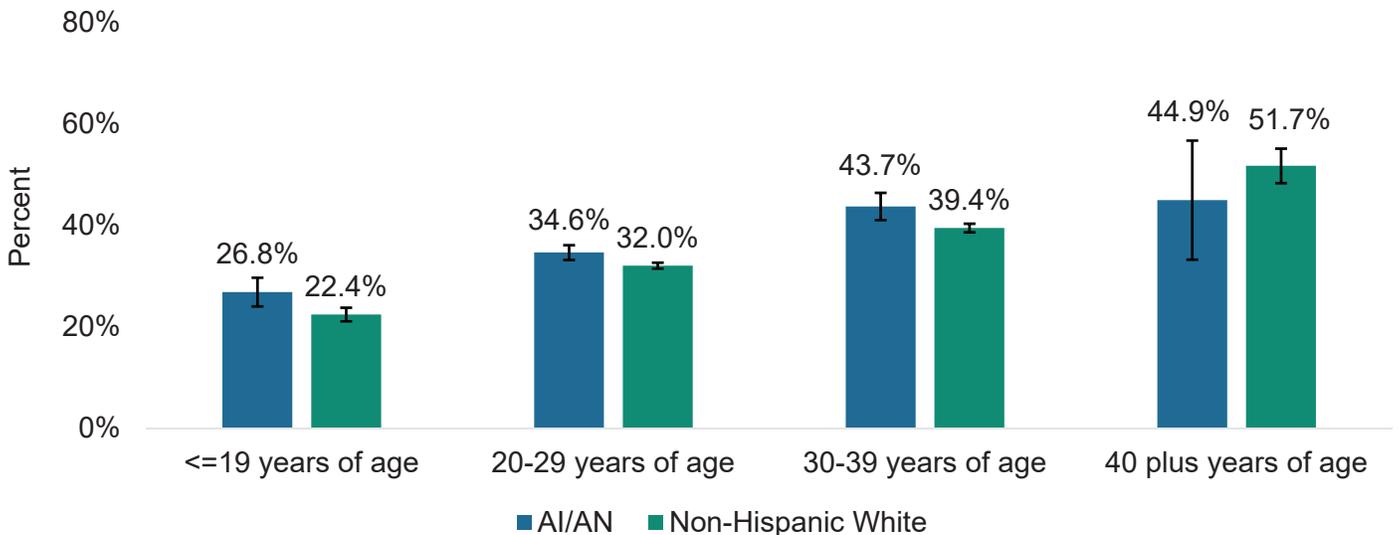

In the Tulsa Service Area, an estimated 35.4% of births were delivered by cesarean section among AI/AN females. This was significantly higher than the proportion of deliveries by cesarean section among NHW births (33.8%; Figure 21). The proportion of cesarean deliveries increased as maternal age increased for both AI/AN and NHW women across teenage women, women in their 20s, and women in their 30s (Figure 22). Additionally, among AI/ANs, the proportion of delivering by cesarean section was 1.3 times higher among women in their 30s compared to women in their 20s.

Gestational Diabetes

A woman with gestational diabetes may have a larger than average baby.³¹ Diabetes during a pregnancy leads to the unborn child having a higher-than-normal blood sugar level, which causes an overproduction of insulin in the unborn child. That overproduction produces extra calories that are stored as fat, making the baby larger than average. Due to the size of the child, there may be delivery complications for both the mother and the baby.

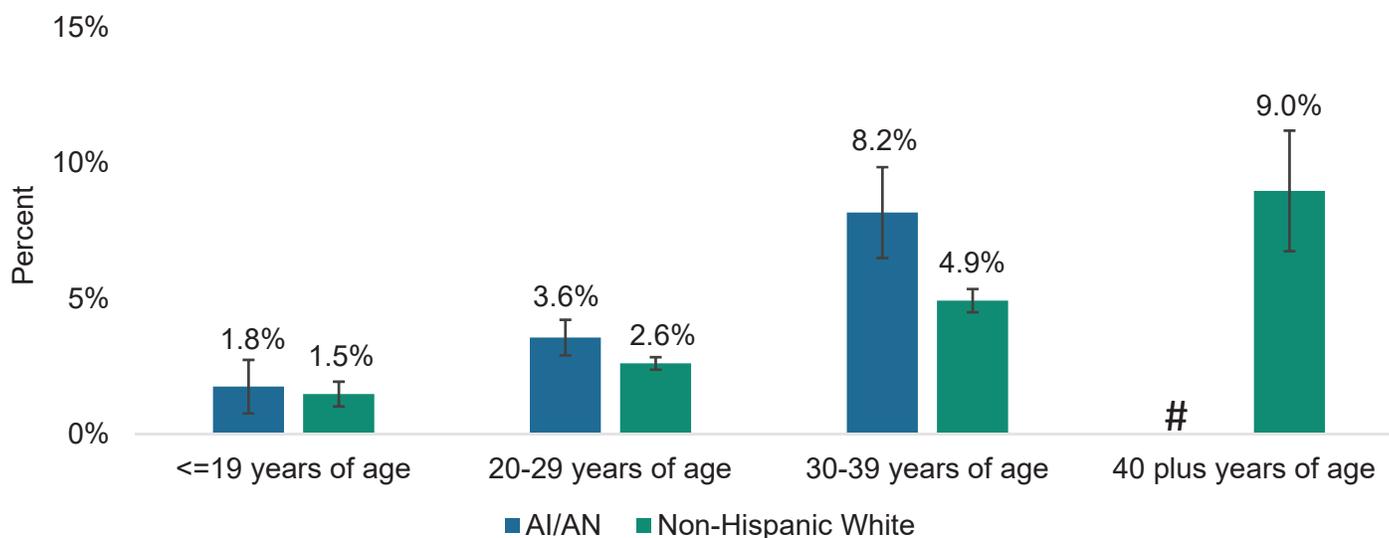

In the Tulsa service area, 4.4% of AI/AN births were to women who were diagnosed with gestational diabetes during their pregnancy, which was 1.3 times higher than their NHW counterparts (Figure 23). This proportion was significantly higher than NHW women, where 3.4% of women giving birth were diagnosed with gestational diabetes. The proportion of women who were diagnosed with gestational diabetes during pregnancy increased as maternal age increased for both AI/AN women and for NHW women (Figure 24). Additionally, among AI/ANs, the proportion of births to women diagnosed with gestational diabetes was 2.3 times higher among women in their 30s compared to women in their 20s.

TULSA SERVICE AREA

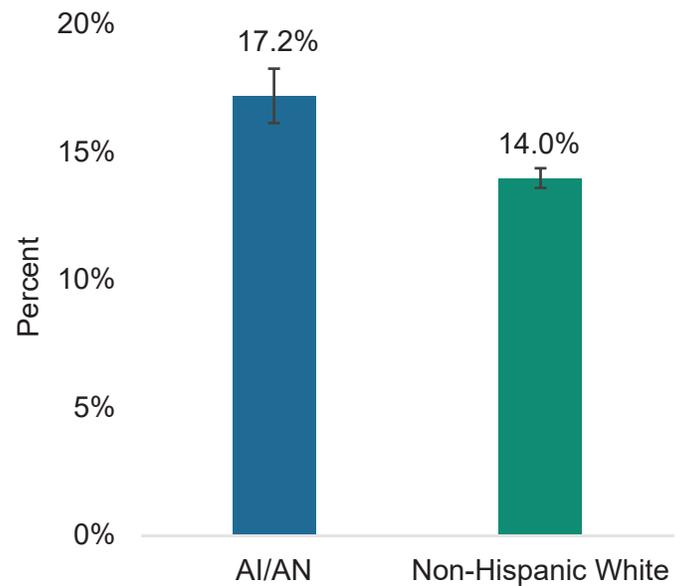

Maternal Smoking

Smoking before and during pregnancy is the single most preventable cause of illness and death among mothers and infants.³² Maternal smoking can result in complications during delivery for both mother and newborn and may result in adverse outcomes for the infant. Complications include low birth weight, preterm birth, ectopic pregnancy, miscarriage, stillbirths, slow fetal growth, placenta previa and abruption, severe vaginal bleeding, intrauterine growth restriction, sudden infant death syndrome (SIDS), and birth defects.

In the Tulsa service area, 17.2% of women smoked while pregnant compared to 14% of NHW women (Figure 25). The proportion of smoking while pregnant was 1.2 times higher in AI/AN women compared to NHW women.

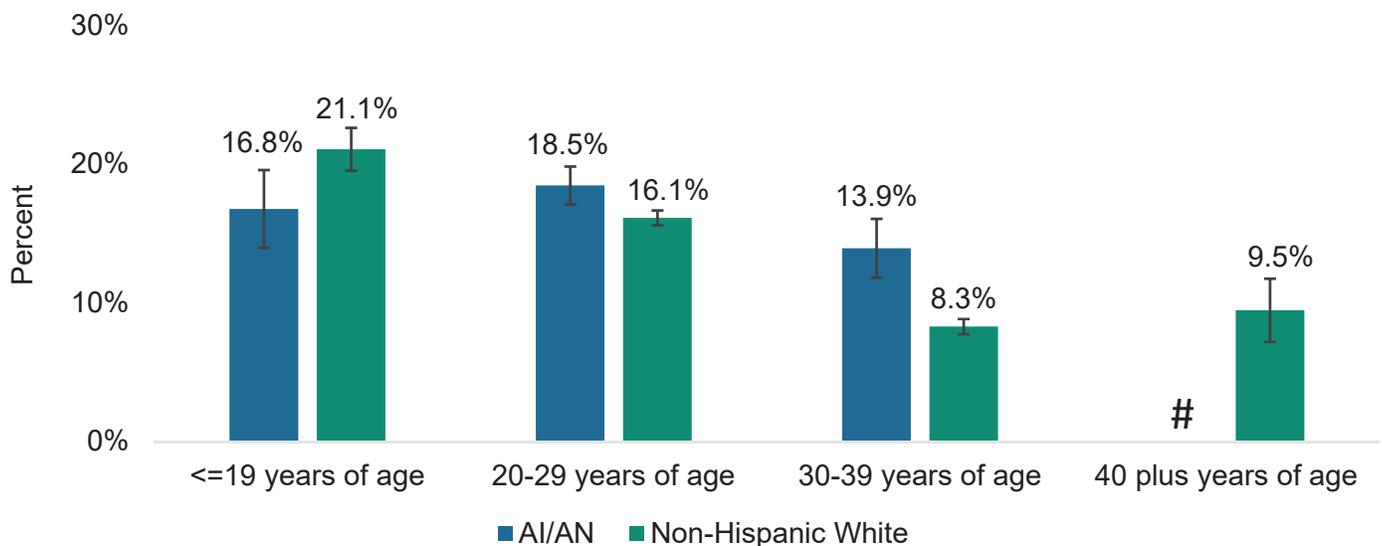

Maternal smoking decreased as maternal age increased for teenage women, women in their 20s, and women in their 30s among NHWs (Figure 26). A difference could be seen between AI/AN women in their 20s and AI/AN women in their 30s, in which women in their 20s were 1.3 times more likely to smoke during pregnancy than women in their 30s.

Prenatal Care

Prenatal care refers to the medical attention received by women before or during their pregnancy. The goal of prenatal care is to detect potential problems early in the pregnancy and to prevent potential complications. Early prenatal care is a significant component in ensuring a good pregnancy outcome and it is recommended for women to begin prenatal care during the first trimester.³³ Women who receive late or no prenatal care are at risk for having undetected complications during their pregnancy that can result in severe maternal morbidity and mortality, and serious consequences to the unborn infant including low birth weight, premature birth, morbidity, and mortality.

Among pregnant women in the Tulsa Service Area, 57.4% of AI/AN women began prenatal care in the first trimester compared to 65.6% of NHW women, a significant difference (Figure 27). The proportion of women beginning prenatal care in their first trimester was 1.1 times higher in NHW women compared to AI/AN women. In addition, 11.8% of AI/AN pregnant women began prenatal care in the third trimester or did not receive any prenatal care during their pregnancy compared to 8.3% of NHW pregnant women. The proportion of women beginning prenatal care in their third trimester or receiving no prenatal care was 1.4 times higher in AI/AN women compared to NHW women.

Infant Mortality Rate

Infant mortality, a useful indicator of the health of a community, is defined as the number of deaths of infants younger than one year of age per 1,000 live births for a given time period. Infant mortality is related to the underlying health of the mother, public health practices, socioeconomic conditions, and the availability and use of appropriate pre- and post-natal health care.³⁴ Causes of infant deaths are primarily due to health problems of the infant or a difficult pregnancy.³⁵

Regarding infant mortality in the Tulsa service area, there was a significant difference between AI/ANs and NHWs (14.3 per 1,000 live births vs. 5.4 per 1,000 live births; Figure 28). The proportion of infant mortality was 2.6 times higher for AI/ANs compared to NHWs.

Figure 28. Infant Mortality Rate, Tulsa Service Area, 2008-2012

Source: National Vital Statistics, Birth Certificates, 2008-2012

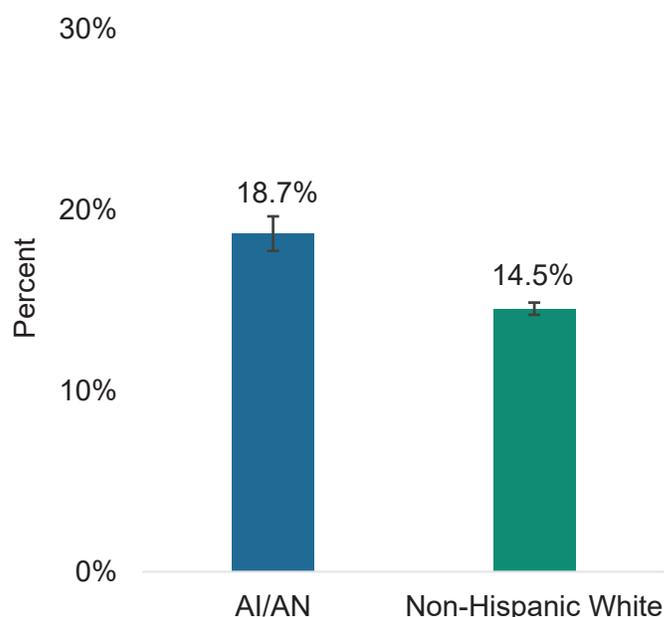

Premature Births

A premature birth is defined as, “childbirth occurring between 20 and 37 completed weeks of pregnancy”.³⁶ Infants born prematurely have an increased risk of health complications, including infant mortality, and are at a greater risk of developing long-term disabilities.³⁷ The risk of adverse outcomes is directly related to the length of a woman’s pregnancy. The shorter the pregnancy, the greater the risk of complications and disabilities in the newborn.

Of all infants born to AI/AN women in the Tulsa service area, 18.7% were born prematurely, which is significantly higher than all infants born prematurely to NHW women at 14.5% (Figure 29). The proportion of premature births to AI/AN women was 1.3 times higher than NHWs.

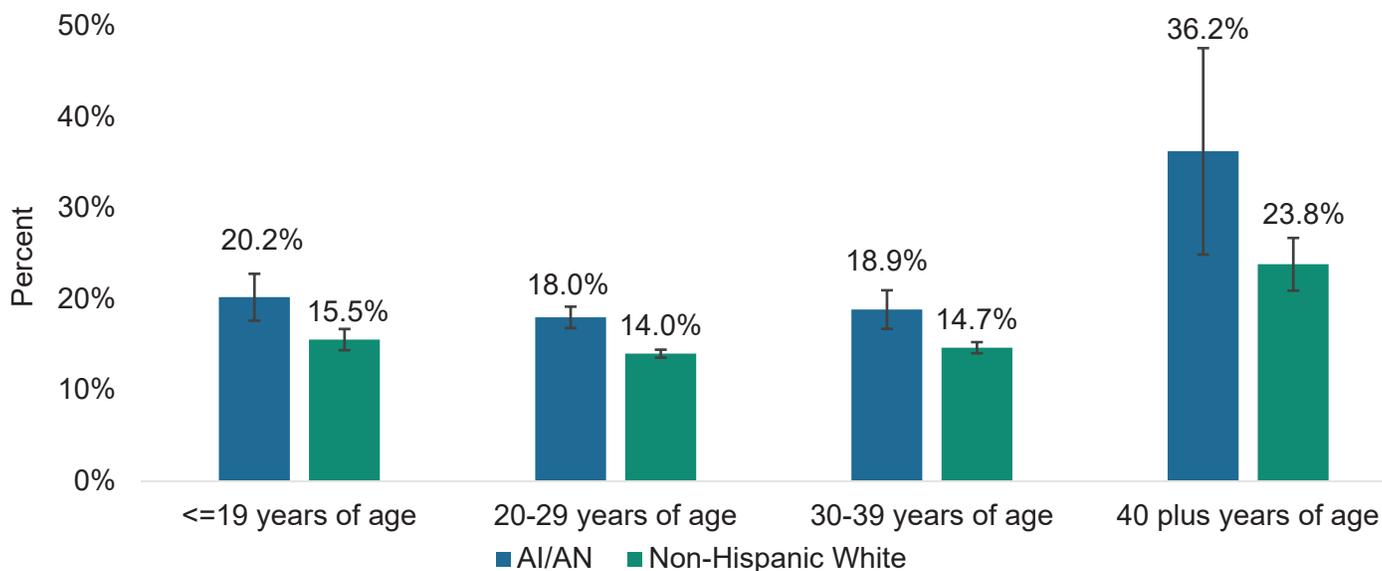

The proportions of premature birth remained relatively similar across maternal age groups for both AI/AN and NHW women, with the exception of women 40 years or older. AI/AN women in their 40s were 1.9 times more likely to have a premature birth than AI/AN women in their 30s. Additionally, AI/AN teenage women were 1.3 times more likely to give birth prematurely compared to their NHW counterparts (20.2% vs. 15.5%; Figure 30).

TULSA SERVICE AREA

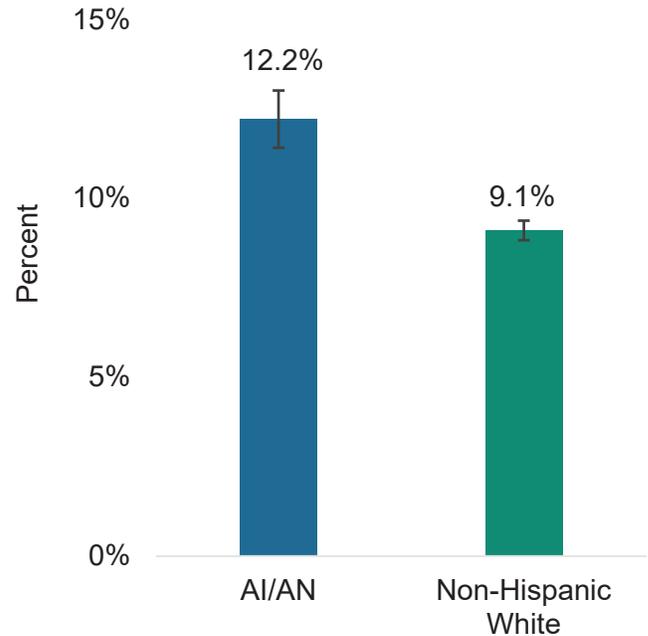

Low Birth Weight

Low birth weight is defined as less than 2,500 grams (5.5 pounds).³⁸ Low birth weight infants have higher rates of subnormal growth, and adverse health conditions.³⁹

In the Tulsa service area, 12.2% of all infants born to AI/AN women were low birth weight, which is significantly higher than low-birth-weight infants born to NHW women (9.1%; Figure 31). The proportion of low birth weight infants born to AI/AN women was 1.3 times higher than infants born to NHW women.

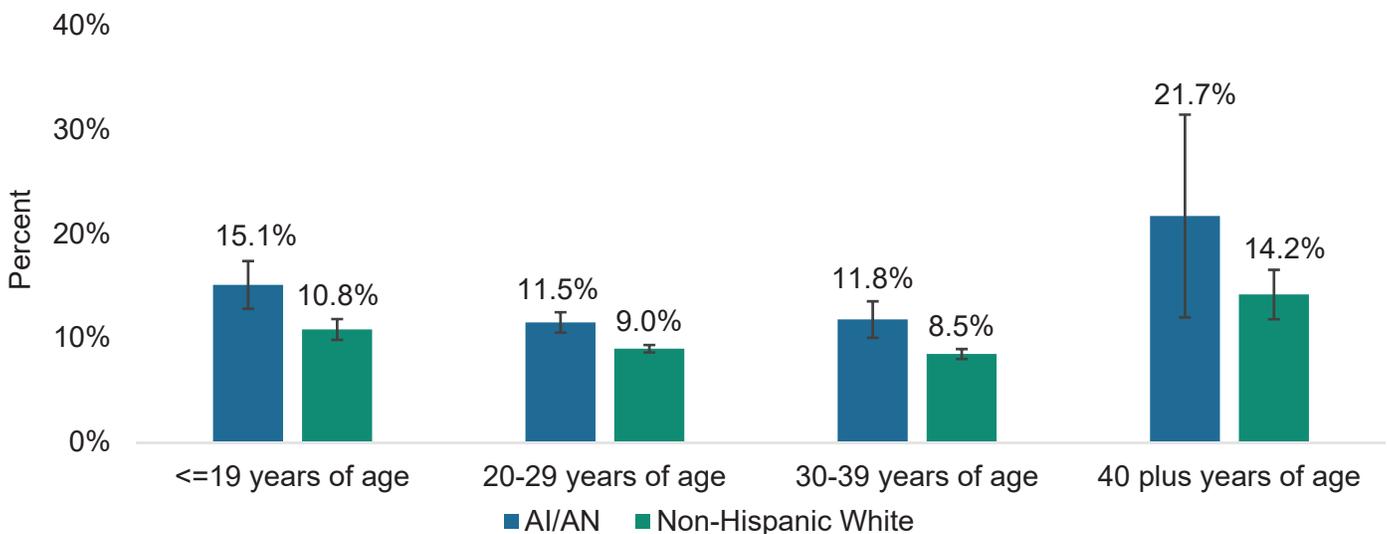

The proportion of low birth weight infants born to AI/AN women remained similar across the maternal age groups. However, there was a difference between the proportion of low birth weight infants born to AI/AN women compared to NHW women for each age group, with the exception of women in their 40s (Figure 32). In particular, among teenage women, AI/AN women were 1.4 times more likely to have a low birth weight infant compared to their NHW counterparts (15.1% vs. 10.8%).

Neonatal Intensive Care Unit Admission

Most babies admitted to the neonatal intensive care unit (NICU) are premature, have low birth weight, or have a medical condition that requires special care. Babies with medical conditions such as heart problems, infections, or birth defects are also cared for in the NICU.^{40, 41}

There was a significantly higher proportion of AI/AN infants admitted to the NICU compared to NHW infants (Figure 33). An estimated 10.9% of AI/AN newborns were admitted to the NICU compared to 8.9% of NHW newborns. The proportion of newborns admitted to the NICU was 1.2 times higher for AI/AN infants compared to NHW infants.

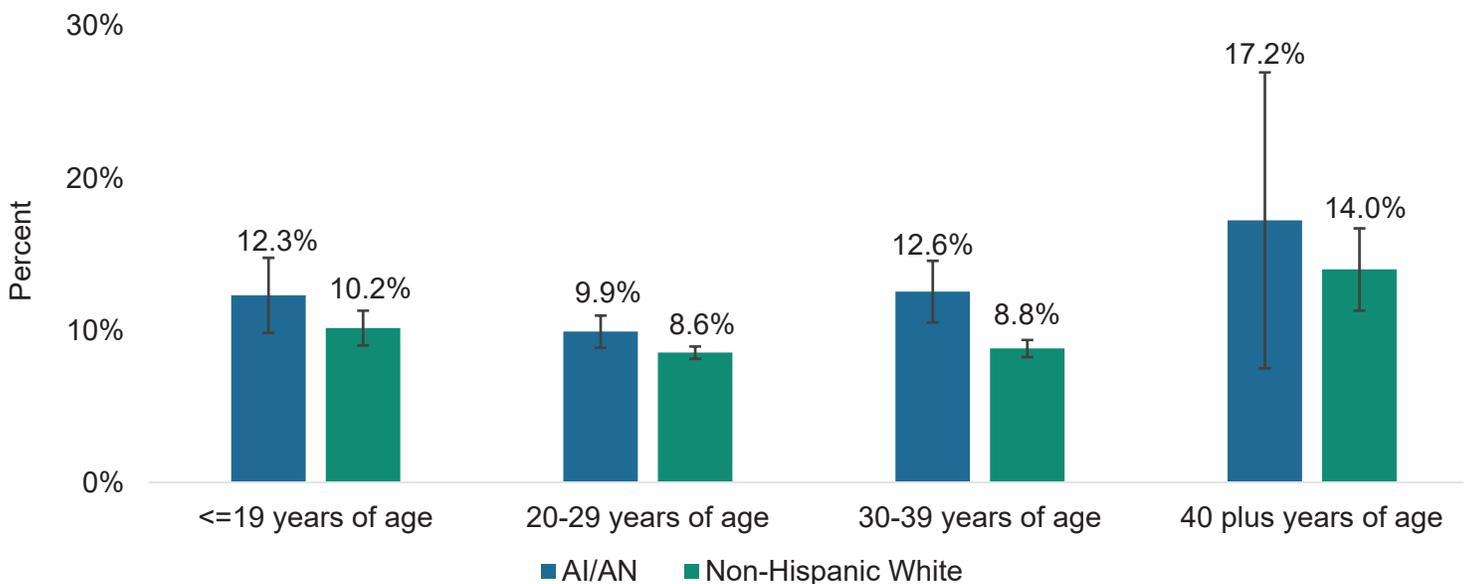

Newborns being admitted to the NICU remained similar across maternal age for AI/AN women (Figure 34); however, a difference was found among women in their 30s and in their 40s for NHWs. Also, among those in their 30s, AI/AN women were 1.4 times more likely to have a newborn admitted to the NICU compared to their NHW counterparts (12.6% vs. 8.8%).
